Introduction Type 2 diabetes is characterized by considerable heterogeneity in its etiopathogenesis and clinical presentation. We aimed to identify clusters of type 2 diabetes in Asian Indians and to look at the clinical implications and outcomes of this clustering. **Research design and methods** From a network of 50 diabetes centers across nine states of India, we selected 19084 individuals with type 2 diabetes (aged 10–97 vears) with diabetes duration of less than 5 years at the

Significance of this study

What is already known about this subject?

- Recently five distinct 'clusters' of individuals with diabetes with significantly different characteristics have been identified in a Scandinavian population.
- The unique Asian Indian phenotype predisposes them to young-onset type 2 diabetes (T2D).

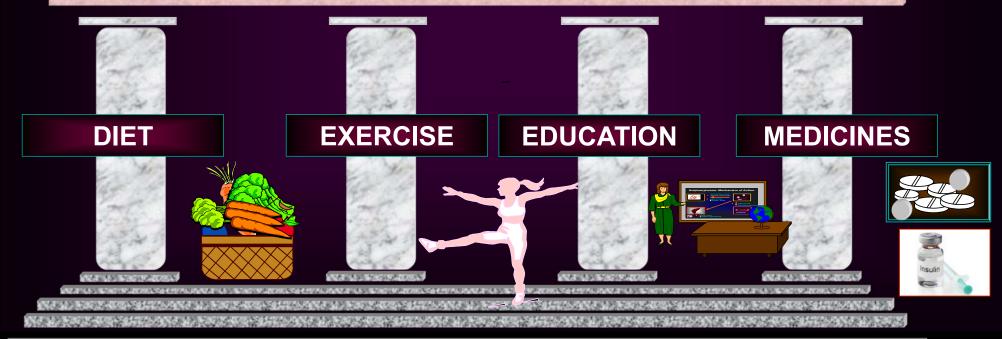

Four subgroups of type 2 diabetes including two novel ones

OBJECTIVE

To derive macronutrient recommendations for remission and prevention of type 2 diabetes (T2D) in Asian Indians using a data-driven optimization approach.

RESEARCH DESIGN AND METHODS

Dietary, behavioral, and demographic assessments were performed on 18,090 adults participating in the nationally representative, population-based Indian Council of Medical Research–India Diabetes (ICMR-INDIAB) study. Fasting and 2-h postglucose challenge capillary blood glucose and glycosylated hemoglobin (HbA_{1c}) were estimated. With HbA_{1c} as the outcome, a linear regression model was first obtained for various glycemic categories: newly diagnosed diabetes (NDD), prediabetes (PD), and normal glucose tolerance (NGT). Macronutrient recommendations were formulated as a constrained quadratic programming problem (QPP) to compute

Choose your plate

ROLE OF EXERCISE

- Blood sugar levels
- Total cholesterol and LDL-Cholesterol
- A HDL-Cholesterol, J Triglycerides
- Blood pressure
- \blacktriangleright \downarrow Weight, body fat, and \uparrow muscle mass
- Insulin resistance
- Alleviates stress
- Prevents diabetes complications

FAR principle

Aerobic Exercise

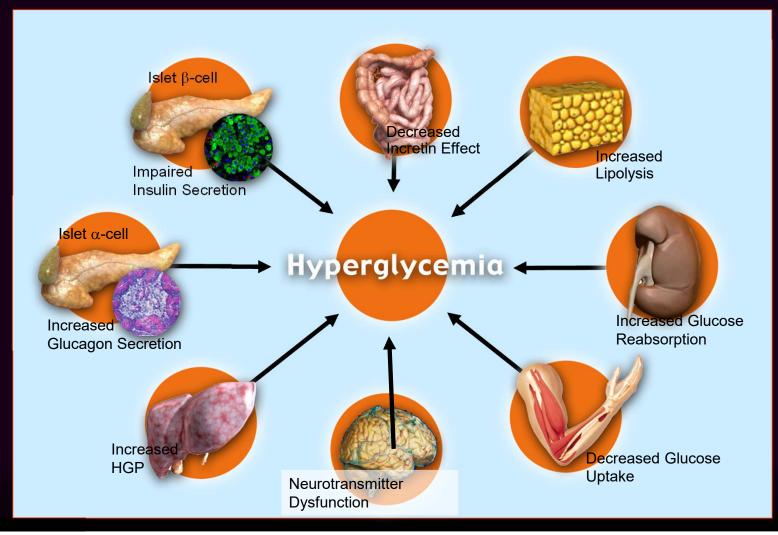

Resistance Training

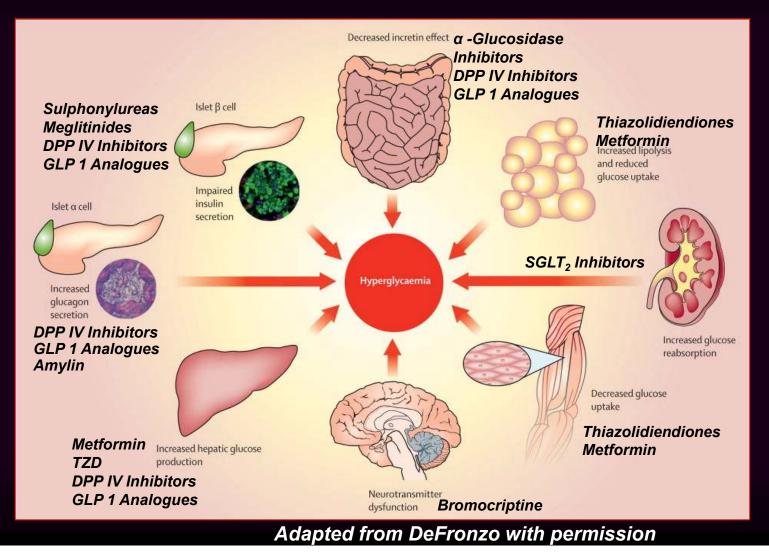

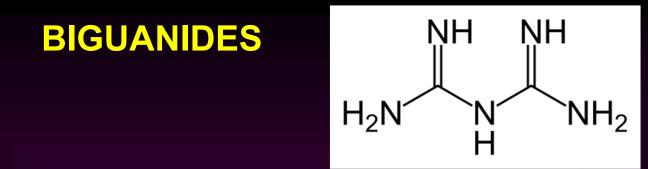

Pharmacotherapy of diabetes

The Ominous Octet

SITES OF ACTION OF ORAL ANTIDIABETIC AGENTS

French Lilac (Gallega officinalis) used for treatment of diabetes from ancient times, contains biguanide

First isolated in the 1920s

First biguanide- phenformin- introduced by Ungar in 1950s

Found to cause lactic acidosis- banned in most countries from 1970s

Metformin- a safer congener of phenformin-introduced in late 1950s

Reintroduced in US in 1995

Now the most widely prescribed anti-diabetic drug in the world

BIGUANIDES

Antidiabetic Efficacy

- Decrease fasting blood glucose ~ 60 mg/dl
- Reduce HbA1c 1.5 2.0%*
- Hypoglycemia rates similar to placebo when used as monotherapy

* Baseline dependent

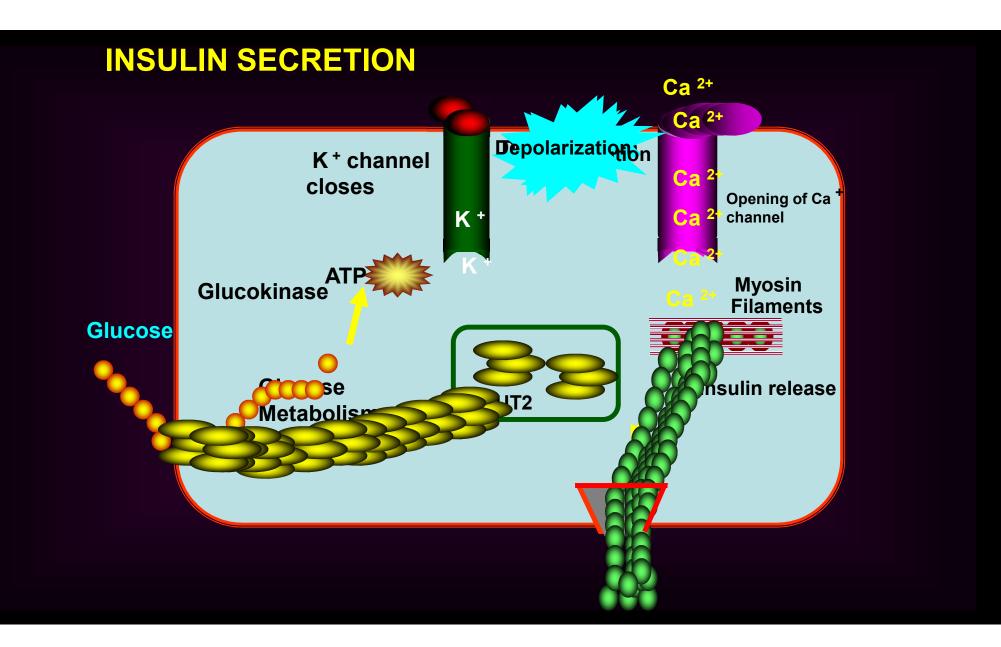

BIGUANIDES

Side effects:

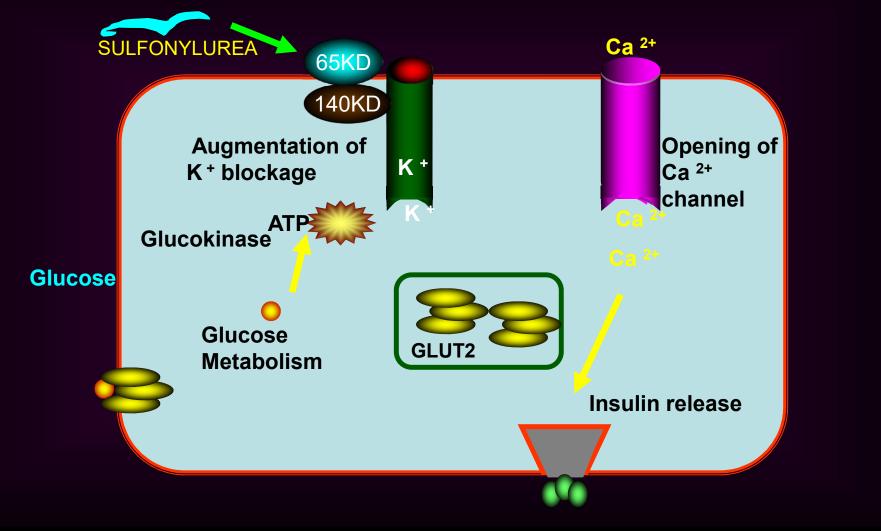

- Diarrhea, abdominal discomfort, nausea, metallic taste, anorexia
- GI side effects can be minimized by starting with a low dose and gradually up - titrating, and by the use of sustained - release preparations
- Mild vitamin B12 deficiency (>2.5 times more likely than in non - users)*
- Metformin Associated Lactic Acidosis (MALA) rare but serious complication (3 to 10 per 100,000 users)[#]

*Data from NHANES (Reinstatler et al, Diabetes Care, 2010) #Inzucchi et al, JAMA, 2014

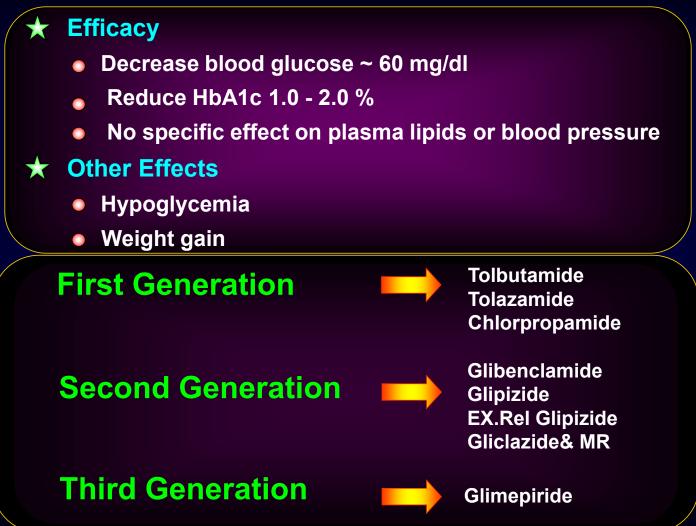

SULFONYLUREAS

SULFONYLUREAS- MECHANISM OF ACTION

SULFONYLUREAS

Sulfonylureas

Pharmacokinetic properties

Drug	Duration of Action (hrs)	Daily dose (mg)
Glibenclamide	20 - 24	2.5 - 10
Gliclazide	10 - 15	40 - 160
Glipizide	12- 14	2.5 - 10
Glimepiride	16 - 24	1 - 4

SULFONYLUREAS

Side Effects

- Hypoglycemia is a common side effect; older agents like glibenclamide can produce prolonged hypos
- To minimize risk of hypoglycaemia, "start low and go slow"
- Weight gain
- Hypersensitivity reactions (including Stevens Johnson syndrome)

ALPHA GLUCOSIDASE INHIBITORS

ALPHA GLUCOSIDASE INHIBITORS (AGI)

Acarbose

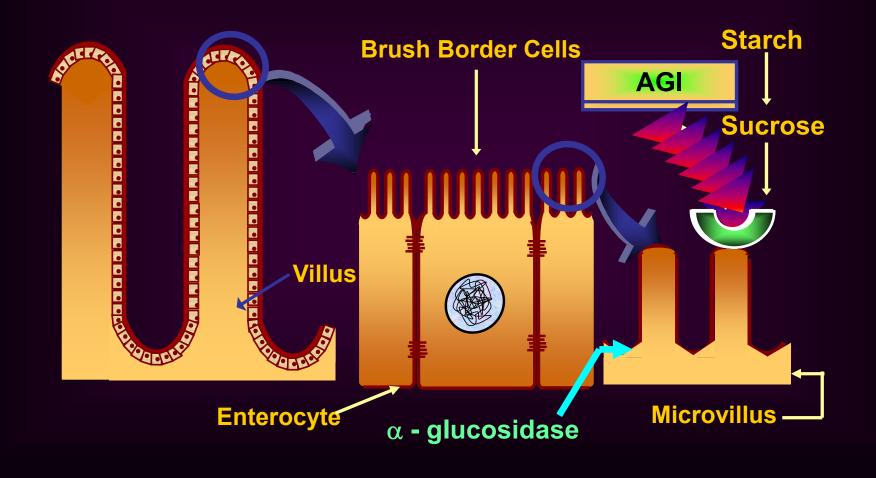

Miglitol

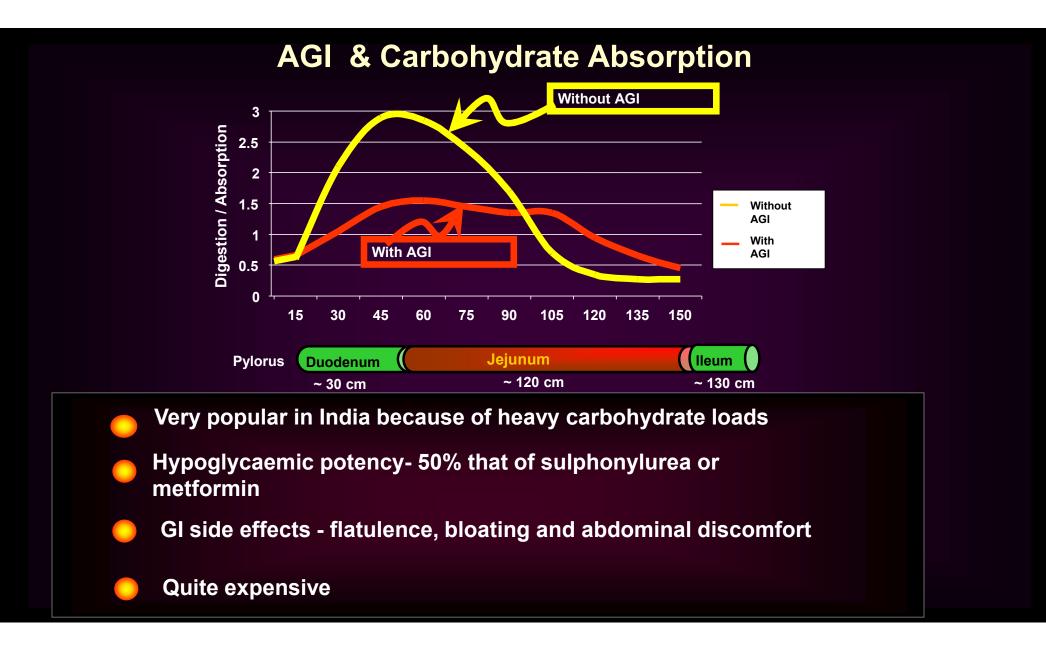

Voglibose

Mechanism of Action of AGI

THIAZOLIDINEDIONES

THIAZOLIDINEDIONES

Antidiabetic Efficacy

The only TZD available in India is pioglitazone

Available in 7.5mg, 15mg and 30mg strengths

Can be given once a day without reference to meal timings

- Slow acting- takes 2 to 3 months to achieve maximum benefit
- Brings down HbA1c by 0.5 to 1.5%*

Pioglitazone also has favorable effects on lipid profile

* Baseline dependent

PIOGLITAZONE

CONTRAINDICATIONS AND CAUTIONS

- Contraindicated in patients with NYHA Class III and IV heart failure
- Contraindicated in pregnancy
- Best avoided in renal insufficiency-risk of fluid retention
- Use with caution in:
 - Patients with anemia
 - Patients with fluid overload of any etiology
 - Postmenopausal women (risk of fractures)
 - Use of glitazones has been associated with macular edema although causality has not been proved
 - Hepatotoxicity has not been reported with pioglitazone; routine monitoring of LFT not recommended
 - Bladder cancer

INCRETIN MIMETICS

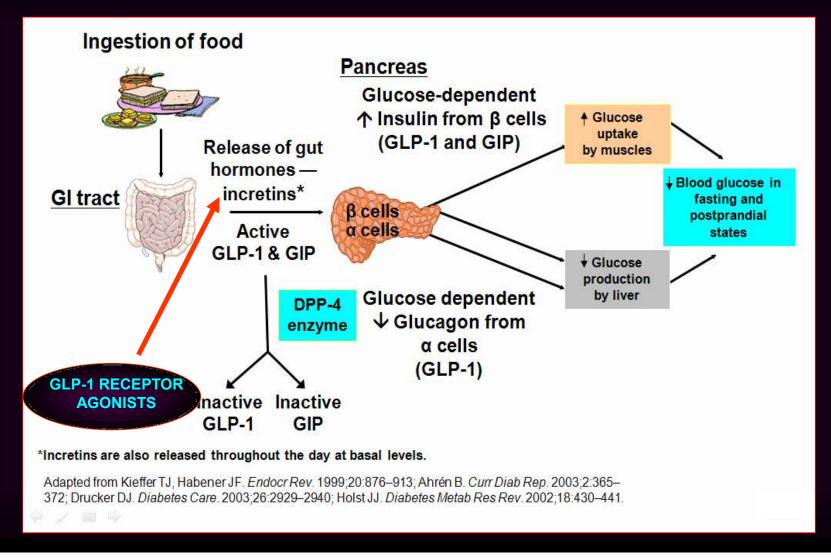

GLP-1 Effects in Humans: Understanding the Glucoregulatory Role of Incretins

Adapted from Flint A, et al. J Clin Invest. 1998;101:515-520.; Adapted from Larsson H, et al. Acta Physiol Scand. 1997;160:413-422.; Adapted from Nauck MA, et al. Diabetologia. 1996;39:1546-1553.; Adapted from Drucker DJ. Diabetes. 1998;47:159-169.

ROLE OF INCRETINS IN GLUCOSE HOMEOSTASIS

Comparison of GLP-1 Receptor Agonists

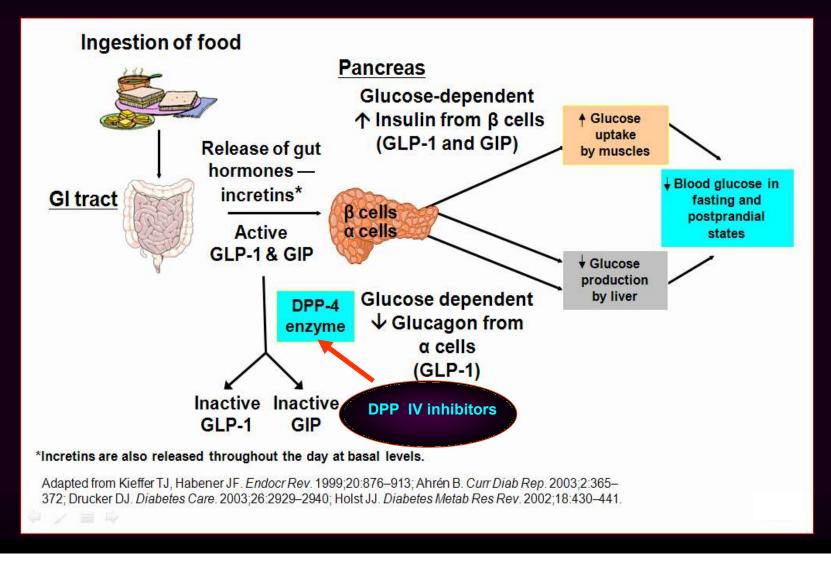

Medication	Dosing frequency	Renal dosing	Relation to meals	Warnings / precautions	
Exenatide LAR	Once weekly SC (2mg)	Caution for eGFR <30; avoid in ESRD	Not related to meals	Pancreatitis, thyroid C-cell cancer	
Liraglutide	Once daily SC (0.6 mg, 1.2 mg, 1.8 mg)	Caution for Cr Clr of 30-50 ml/min	Not related to meals	Pancreatitis, thyroid C-cell cancer; MEN type 2	
Dulaglutide	Once weekly SC (0.75 mg, 1.5 mg)	No dosage adjustment	Not related to meals	Thyroid C-cell cancer; Pancreatitis	
Lixisenatide	Once daily SC (10-20 mcg)	Not recommended in severe renal impairment	Within 60 min before a meal	Pancreatitis	
Semaglutide	Once weekly SC (0.25 to 1mg)	No dosage adjustment	Not related to meals	Thyroid C-cell cancer; Pancreatitis; Monitor for	
	Once daily PO (3, 7 and 14mg)		On empty stomach; Nothing by mouth for 30 min after pill intake	retinopathy progression

ARTICLE INFO

ABSTRACT

Article history: Received 8 May 2008 Received in revised form The efficacy and safety of sitagliptin as monotherapy were evaluated in Chinese, Indian, and Korean patients with type 2 diabetes inadequately controlled by diet and exercise. In a randomized, placebo-controlled, double-blind, 18-week trial, 530 patients with HbA_{1c} \geq 7.5%

Results: Efficacy Change from Baseline in HbA1c

Country	Placebo subtracted % A1c change * Baseline 8.74%	95% Confidence limits
India	- 1.36	(- 1.73, - 0.99)
China	- 0.69	(- 0.92, - 0.46)
Korea	- 1.38	(- 1.92, - 0.83)

Mohan V et al. *Diabetes Res Clin Pract*. 2009;83:106–116.

DPP-IV Inhibitors – Adverse effects

- Generally well tolerated
- Rarely can produce common cold like symptoms and nausea
- Incidence of hypoglycemia similar to placebo when used as monotherapy
- A few cases of acute pancreatitis have been reported during postmarketing surveillance of sitagliptin & vildagliptin. Cause and effect relationship has not been established.

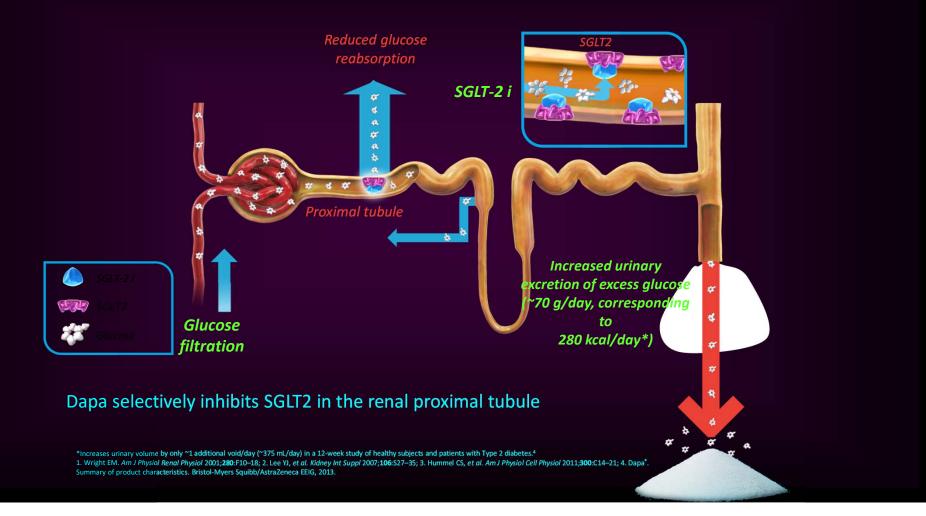

SGLT2 INHIBITORS

SGLT-2 Inhibition: A novel insulin-independent approach to remove excess glucose

SGLT2 INHIBITORS

Canagliflozin, dapagliflozin and empagliflozin

- Bring about a reduction in HbA1c of 0.7 to 1.0% compared to placebo
- Minimal risk of hypoglycemia
- Dose ranges from 100-300 mg/day (Cana), 5-10 mg/day (Dapa) and 10-25 mg/day (Empa) as a single daily dose

 Dosage reduction is needed in renal insufficiency (Cana); contraindicated if eGFR < 60 ml/min/1.73 m² (Dapa) or <45 ml/min/ 1.73 m² (Empa)

SGLT2 INHIBITORS

Additional benefits

- Modest weight loss (approx. 2 kg)
- Can be used at any stage of type 2 diabetes
- Lowering of systolic and diastolic BP (2-4/1-2 mmHg)
- Improvement in all-cause mortality and CV outcomes (empagliflozin)*

Side effects

- Generally well tolerated; adverse effects include genital mycotic infections (11% higher in women and 5% higher in men compared to placebo). Symptoms related to volume depletion may also occur
- Occasional reports of euglycemic ketoacidosis (especially when used off-label in T1DM)
- Lower limb fracture (Canagliflozin)

Efficacy of Modern Diabetes Treatments DPP-4i, SGLT-2i, and GLP-1RA in White and Asian Patients With Diabetes: A Systematic Raviow and Mota **Conclusion :** The glucose lowering efficacy of SGLT-2i, and **DPP-4i**, was greater in studies of predominantly Asian ethnicity compared to studies of predominantly white

ethnicity.

FACTORS INFLUENCING ANTIDIABETIC DRUG SELECTION

Drug characteristics

- Efficacy (HbA1c lowering)
- Risk of hypoglycemia
- Risk of weight gain
- Ease of use
- Other side effects & tolerability issues

Patient characteristics

- Presence of co-morbidities (e.g. renal failure)
- Age
- Affordability

IMPACT OF THERAPIES ON HbA1c LEVELS

Therapy	HbA1c Reduction*		
Diet and Exercise	0.5 - 2.0%		
Sulfonylureas	1.0 - 2.0%		
Metformin	1.0 - 2.0%		
Thiazolidinediones	0.5- 1.0%		
α-Glucosidase Inhibitors	0.5- 0.8%		
DPP-IV inhibitors	0.5- 1.0%		
SGLT-2 inhibitors	0.5- 1.0%		
Incretin mimetics	Around 1%		
Insulin	> 5% (Unlimited)		

* Baseline dependent

However, there is a great deal of interindividual variation in response to antidiabetic therapy

Adapted from Nathan D. N Engl J Med, 2002. 347, 17

58

RISK OF HYPOGLYCEMIA

- In general, drugs that increase insulin levels are associated with an increased risk of hypoglycemia.
- An exception to this rule is the incretin-based agents, which cause glucose-dependent insulin secretion and hence no hypoglycemia.
- SU and glinides are the antidiabetic agents most associated with hypos.
- TZDs, Metformin, AGIs, DPP 4i, SGLT2i are associated with minimal risk of hypos when used as monotherapy.
- However, these agents can potentiate the hypos caused by SU and glinides

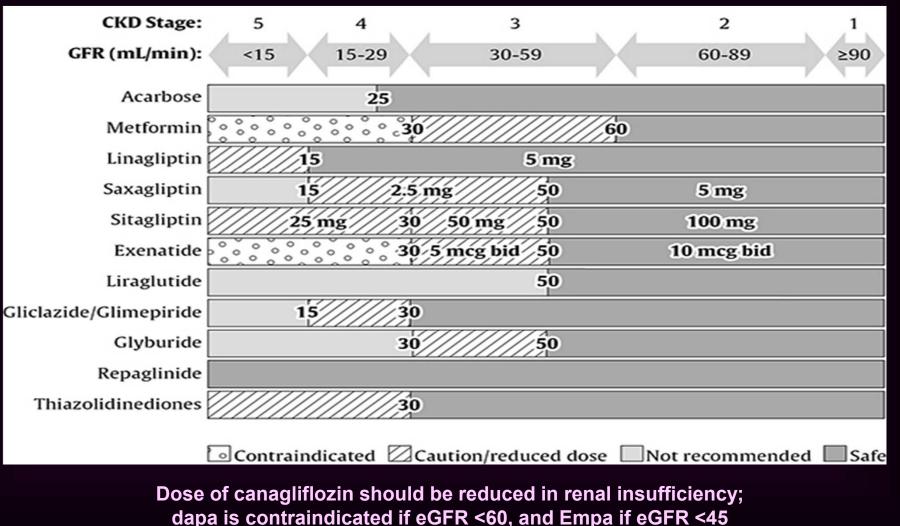

ANTIDIABETIC AGENTS AND WEIGHT

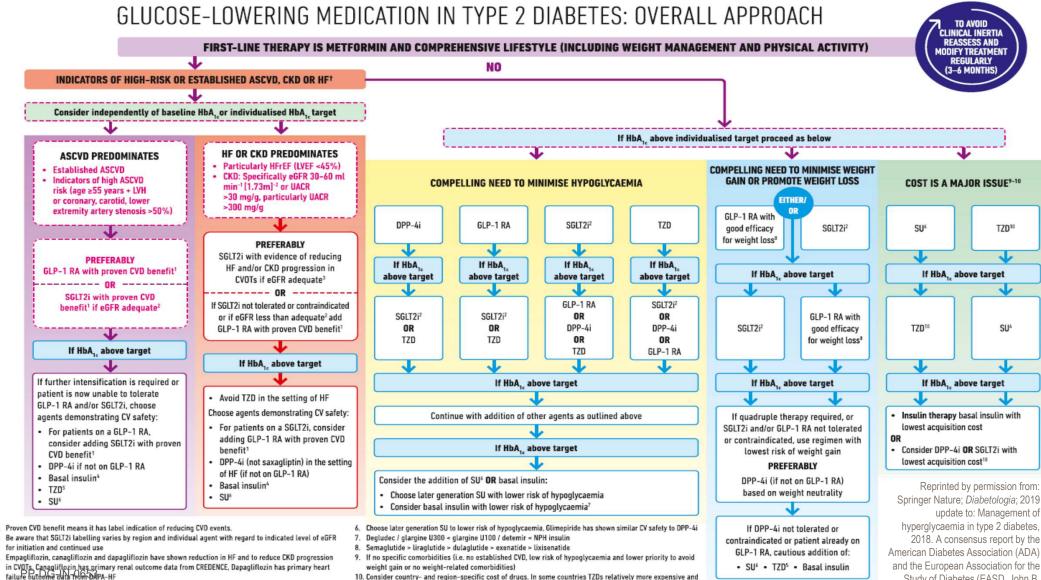

Class	Agent(s)	Weight Effect
Amylin analog	Pramlintide	\downarrow
Biguanide	Metformin	\downarrow
GLP-1 receptor agonists	Albiglutide, dulaglutide, exenatide, exenatide XR, liraglutide	Ļ
SGLT-2 inhibitors	Canagliflozin, dapagliflozin, empagliflozin	\downarrow
α-Glucosidase inhibitors	Acarbose, miglitol	\leftrightarrow
Bile acid sequestrant	Colesevelam	\leftrightarrow
DPP-4 inhibitors	Alogliptin, linagliptin, saxagliptin, sitagliptin	\leftrightarrow
Dopamine-2 agonist	Bromocriptine	\leftrightarrow
Glinides	Nateglinide, repaglinide	↑
Sulfonylureas	Glimepiride, glipizide, glyburide	1
Insulin	Aspart, detemir, glargine, glulisine, lispro, NPH, regular, inhaled	$\uparrow\uparrow$
Thiazolidinediones	Pioglitazone, rosiglitazone	$\uparrow\uparrow$

- Risk of additional weight gain must be balanced against the benefits of the agent
 - Sulfonylureas may negate weight loss benefits of GLP-1 receptor agonists or metformin
 - Insulin should not be withheld because of the risk of weight gain

ANTIDIABETIC DRUG DOSING IN RENAL INSUFFICIENCY

Study of Diabetes (EASD, John B.

4. Degludec and U100 glargine have demonstrated CVD safety

- weight gain or no weight-related comorbidities)
- 10. Consider country- and region-specific cost of drugs. In some countries TZDs relatively more expensive and DPP-4i relatively cheaper

CONCLUSIONS

The pathophysiology of T2D is multifactorial.

- We now have OADs acting on most of the known pathophysiological defects in T2D.
- Metformin is widely accepted as the first-line agent for T2D, but most patients will need additional medications to control diabetes sooner or later.
- Choice of subsequent agents is decided based upon drug factors (efficacy, side effects) and patient factors (age, affordability, co-morbidities).
- Always discuss options with the patient!
